Energy, Mobility,  
Innovation and Technology

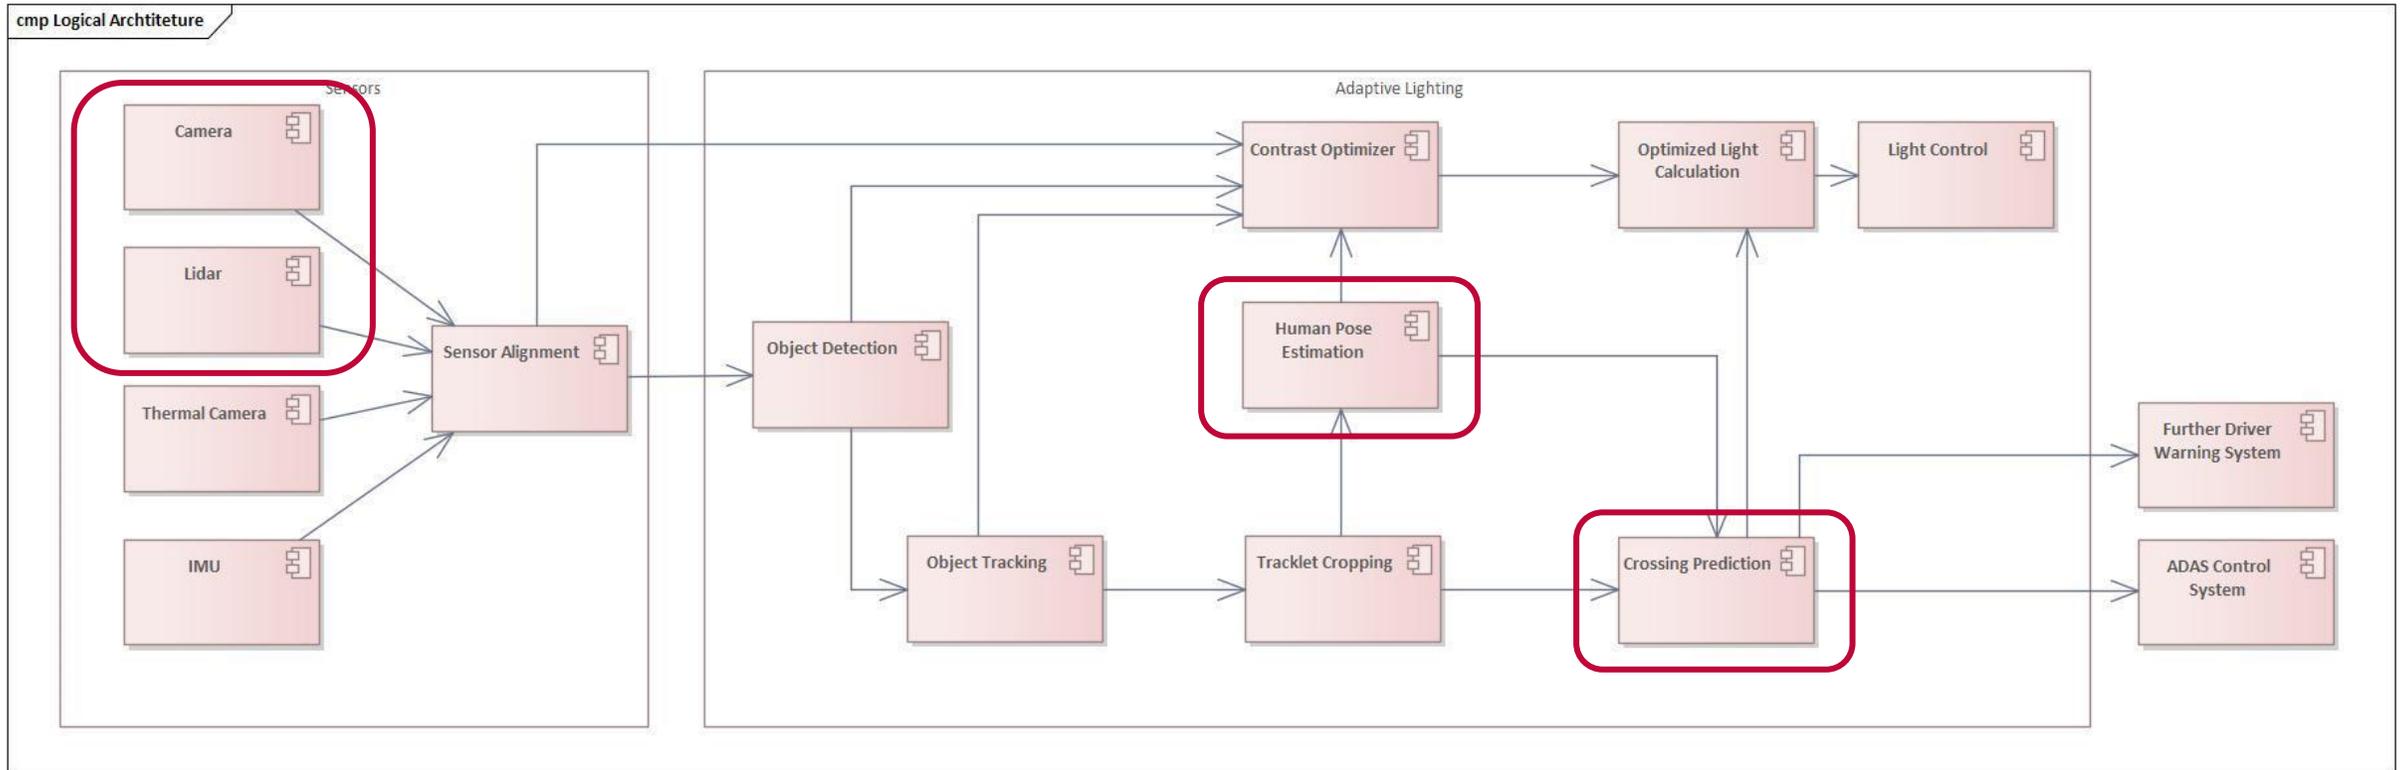

> Started 2020, ended 06/2023

> Consortium:

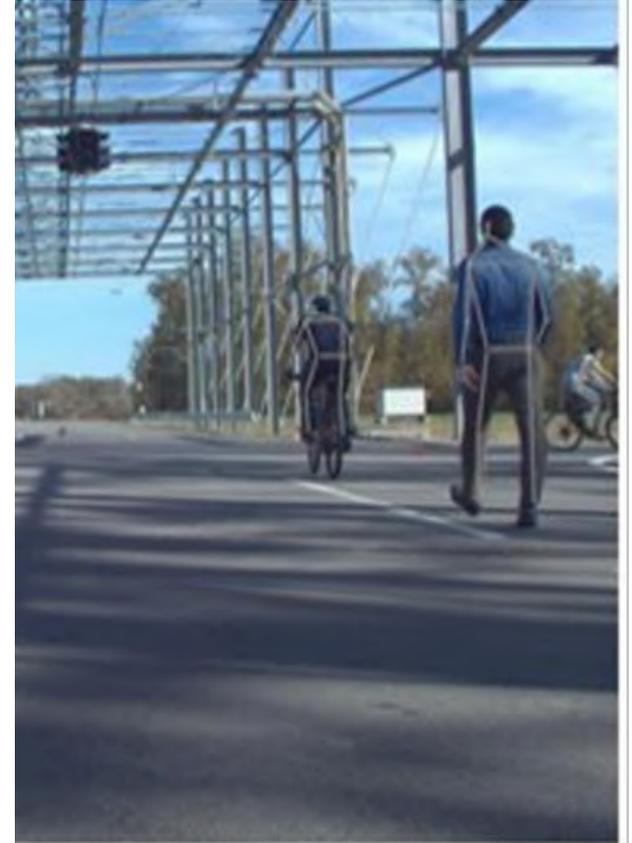

> GOAL: Development of a robust sensor system that is capable to predict the behavior of VRUs

- > Detect VRUs
- > Predict the intention and possible crossing
- > Approach:
  - > Fusion of camera and LiDAR data
  - > Extract pose and localization
  - > Transfer information to intention prediction algorithm

## > Goals:

- > Develop procedures to analyze and extrapolate the paths of VRUs
- > Develop prediction whether VRU path crosses driving path of ego vehicle (potential hazard)

## > Approach

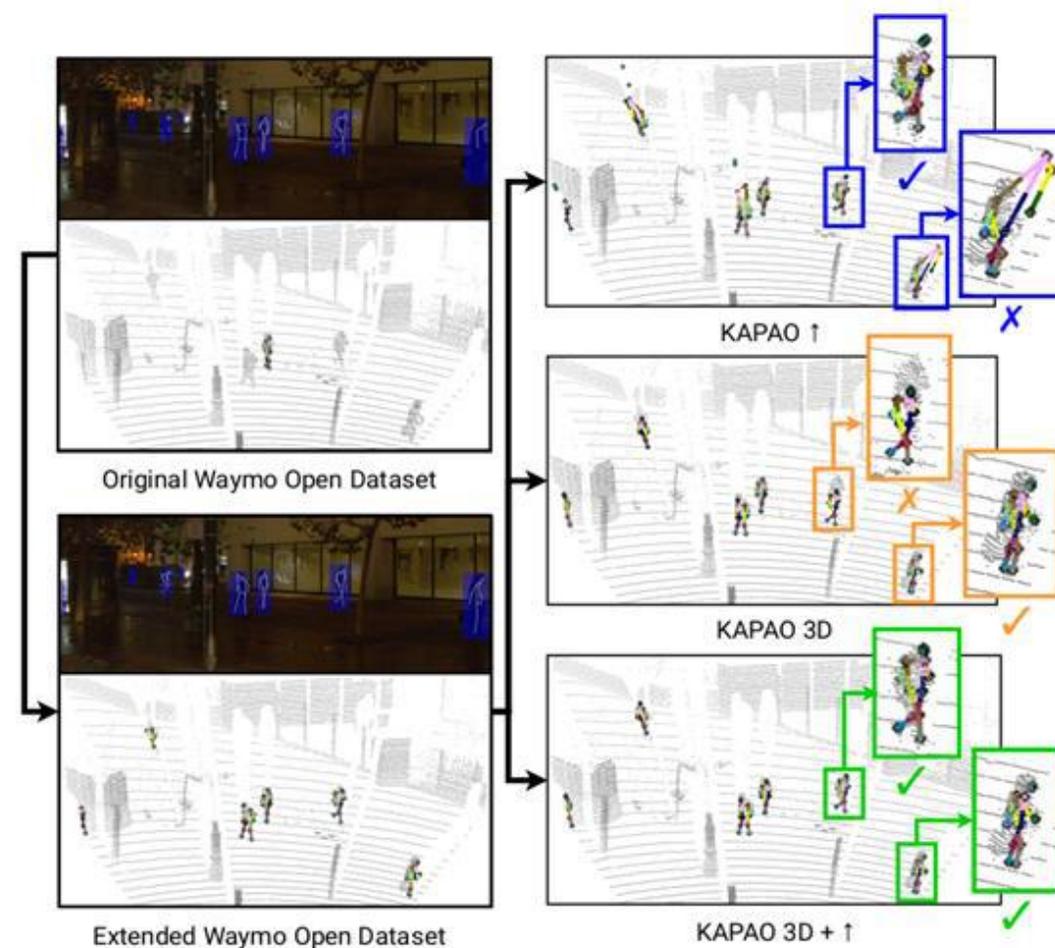

- > Fuse data from different modalities
- > Combine position, size, **pose** and visual representation of VRUs

- > Basic principle: use a robust 2D pose estimation and extend it to 3D
- > Idea: use KAPAO
  - > KAPAO = *keypoints and poses as objects*
  - > Efficient single-stage multi-person human pose estimation
  - > Simultaneous detection of pose objects and keypoint objects, fused to predict human poses

Source: <https://github.com/wmcnally/kapao>

- > Three approaches to add 3D information
  - > **KAPAO Lift (↑)**: add depth information from LiDAR (LiDAR Lift)
  - > **KAPAO 3D**: estimate depth directly from images
  - > **KAPAO 3D+Lift(↑)**: use LiDAR Lift to correct depth estimation from images
- > Create 3D dataset to compare performance of each approach
  - > Use Waymo open dataset (2D)
  - > Extract 3D information and add it to the dataset = extended Waymo open dataset (3D)
- > Test each approach against recorded and annotated measurement data
  - > Zalazone
  - > Digitrans
  - > Public road Vienna

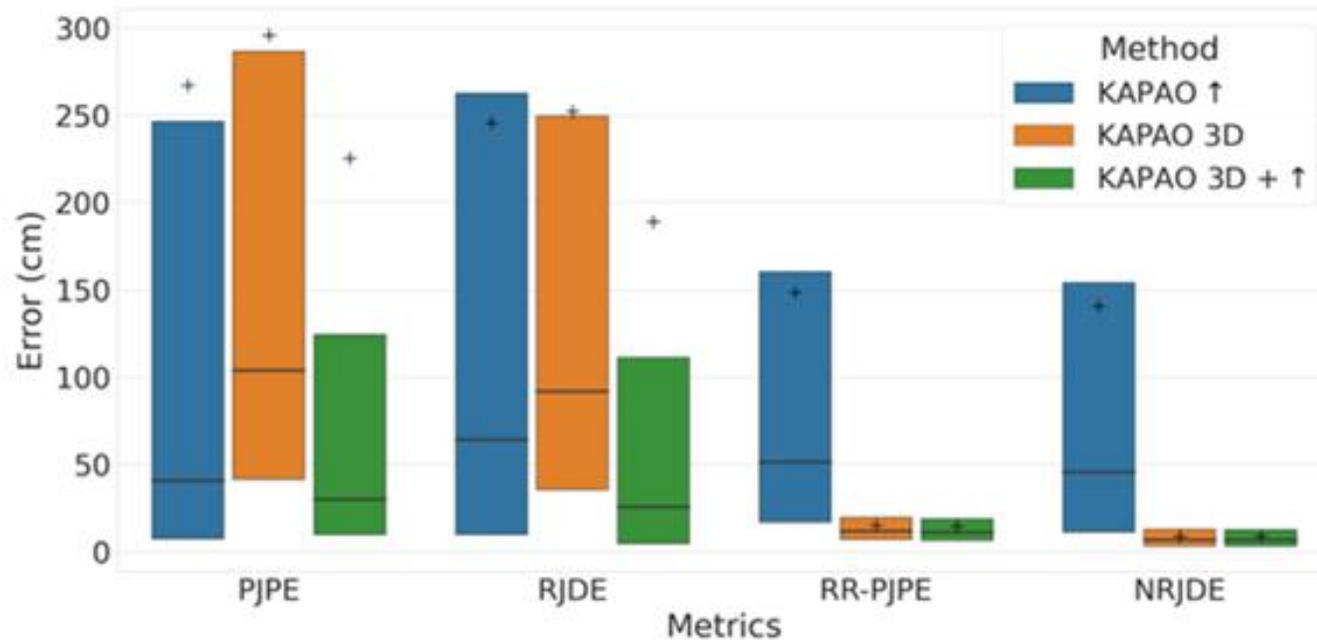

## > Quantitative analysis

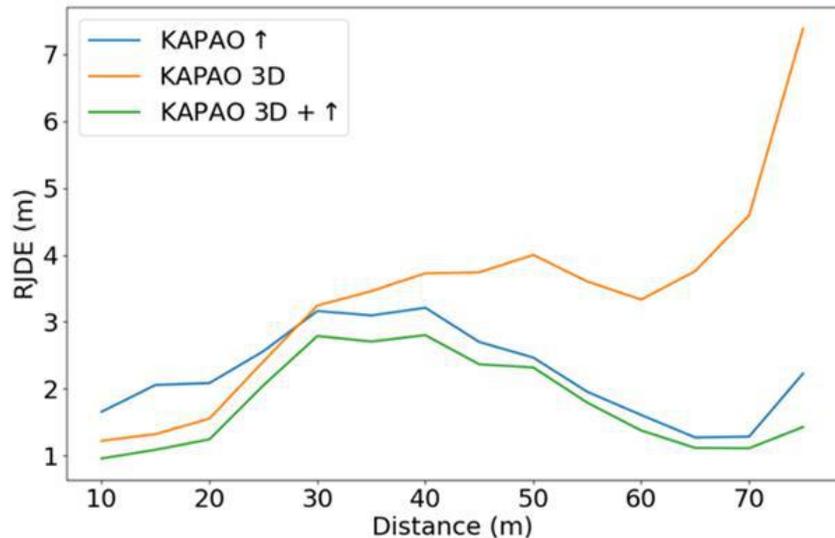

- > **Per joint position error**, absolute (PJPE) and relative against root (RR-PJPE)
- > **Joint depth error**, absolute (RJDE) and relative against root (NRJDE)

## > Summary

- > Absolute errors lower with LiDAR data
- > Relative position errors better with camera

- > Quantitative analysis, part 2
  - > Evaluate each metric over distance between sensor and person

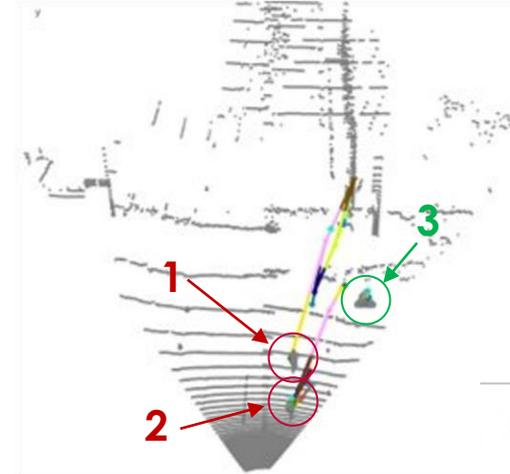

Example: absolute depth error (RJDE) over distance

- > Summary
  - > Accuracy of camera decreases over distance
  - > Lidar produces better results at higher distances
  - > **KAPAO 3D + Lift delivers satisfying performance**

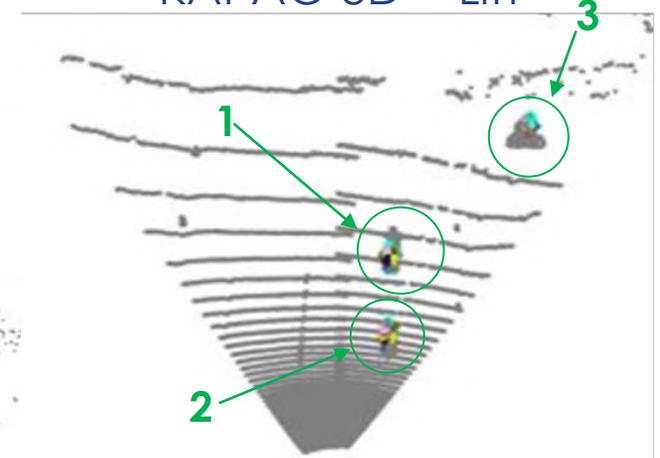

- > Qualitative analysis
  - > Take measurement data and process them through KAPAO 3D + Lift
- > Digitrans data
  - > Reference image at daytime

KAPAO Lift

KAPAO 3D + Lift

KAPAO 3D

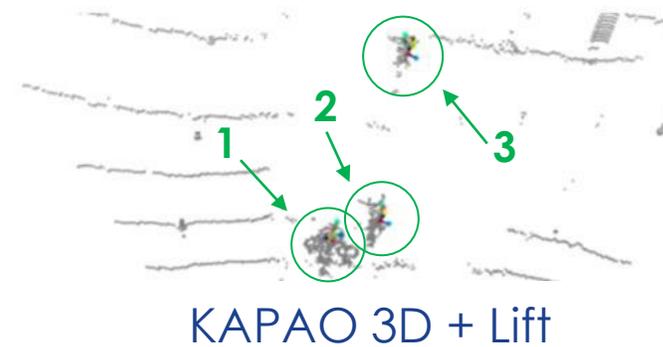

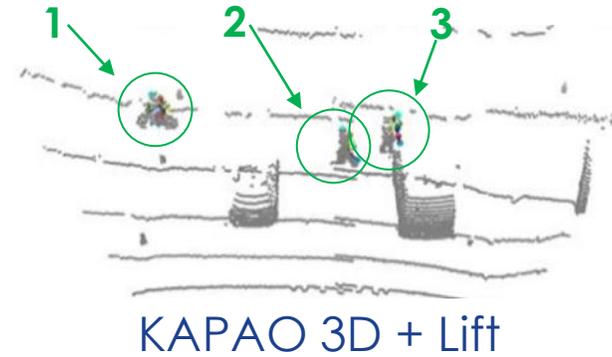

## > Digitrans data

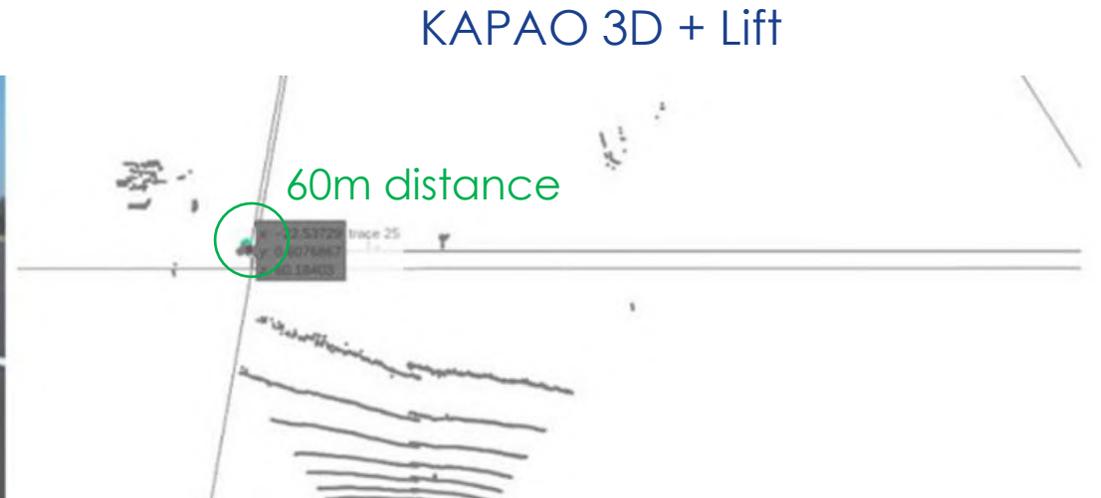

### > Reference image at night-time

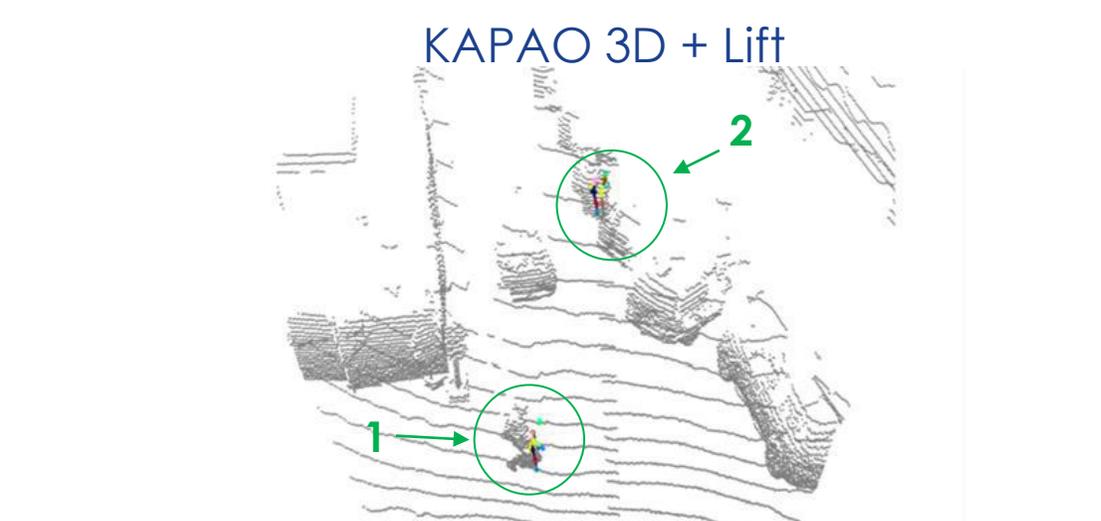

### > Night-time + rain

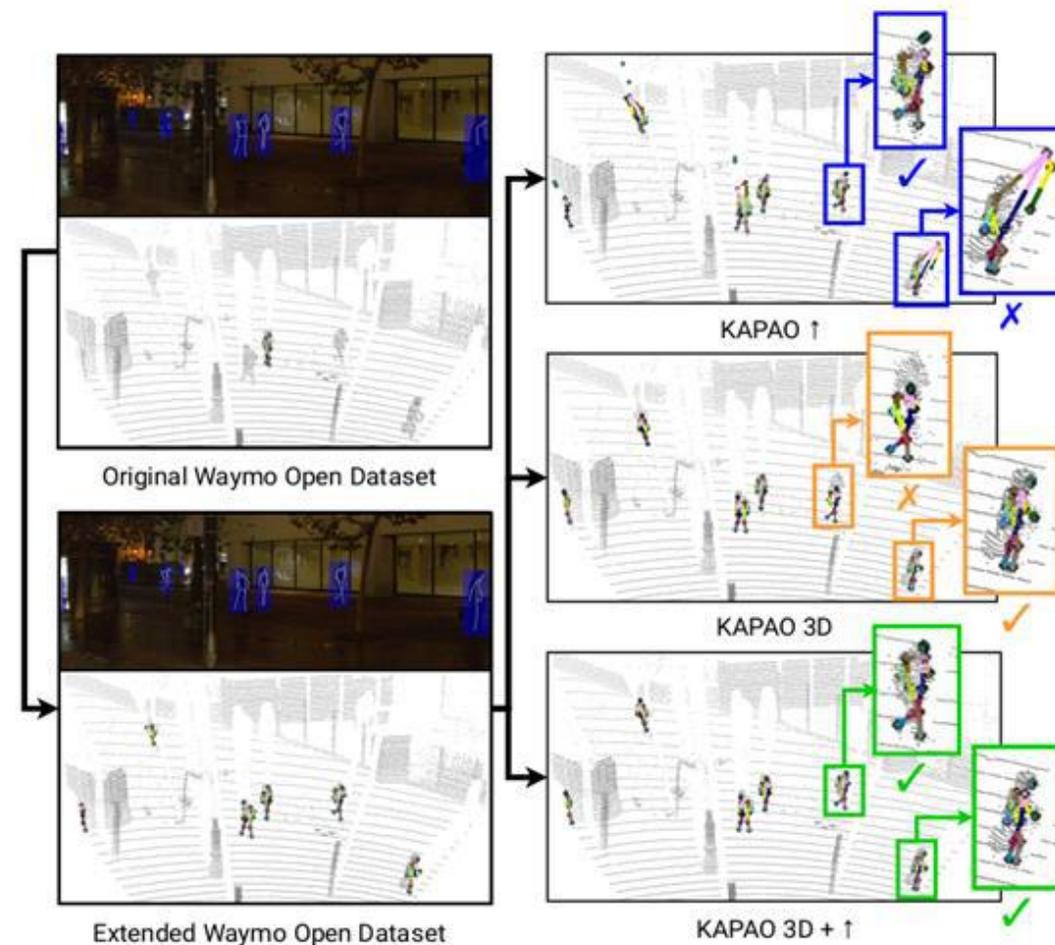

## > Zalazone data

## > Vienna data

- > Fused data from cameras and LiDAR
- > Processed by “KAPAO 3D + Lift” approach
- > Increases detection accuracy while neglecting unplausible results
- > Robust foundation for intention prediction

- > **Combining LiDAR with camera(s)** gives a **significant improvement of pose interpretation** compared to camera-only
- > **Realtime execution possible** on embedded hardware architectures with **trade-off** between **performance and necessary resolution**
- > Further improvement by light support in dark / unlit environment
